Overview

Most of Montana, including the Blackfoot, has likely seen peak snowpack in April. In the Blackfoot, snowpack peaked on April 6 with 21.1 inches of snow-water equivalent (SWE). Normal peak snowpack for the basin is on April 10 with 18.6 SWE. Overall temperatures in April were below average across the State with some significant outliers early in the month and again late in the month. Coming into May, snowpack and river flows are beginning to change dramatically given the unseasonably warm temperatures we’ve seen in late April and early May. In just one-week (from April 25-May 3) snowpack has fallen from 100% to 82% of normal in the basin for this time of year. In one month’s time, flow in the Blackfoot River has increased from less than 40% of normal in early April to around 250% of normal at the beginning of May. Cooler temperatures and precipitation in the few days has steadied the melt-off surge.

The slightly above average snowpack conditions for the basin continue to drive above average streamflow predictions for the basin. The timing of the flow is still something to watch. Runoff is off to an early and above average start; the Blackfoot has already surpassed maximum discharge from last year. We are hoping for more seasonable temperatures through this month to help keep snowpack for longer and prolong runoff later into spring. The 90-day forecast calls for above average temperatures and below normal precipitation. Soil moisture across the State and in the Blackfoot is generally in much better shape this year than last year.
Blackfoot River Basin Snow Water Equivalent

Reservoir Storage

Reservoir levels are generally near normal for this time of year. Nevada Creek Reservoir is currently 92% of normal which is significantly better than it was this time last year at 78%.
